

To update existing commits to use Git LFS for large files, you need to rewrite your repository's history. This is typically done using `git lfs migrate`.

Use `git lfs migrate import` to identify and convert large files in your history to Git LFS pointers.

```
git lfs migrate import --everything
```

Caution: Rewriting history changes commit hashes. If you are working in a shared repository, this will require all collaborators to re-clone or rebase their work, potentially causing disruption. Push the rewritten history.

After the migration, you need to force push the changes to your remote repository.

```
git push --force origin <your-branch-name>
```

This command overwrites the remote history with your local, LFS-enabled history.
